Brandy Gonzales

We each worked independently. I uploaded the notebook to Collab and ran every cell. Logistic Regression scored 88.9% and the Decision Tree scored 83.3%. I tested other sets of three features. Proline, total phenols, and flavonoids scored 91.7%, and so did proline, total phenols and od280. Sets with malic acid scored as low as 66.7%. One choice I made was to keep proline and total phenols, because those two carried the improvement. My run lifted the score from 88.9% to 91.7%. If a teammate asked what the confusion matrix shows, I would say the diagonal is the correct guesses and the other squares are the misses.

Derrick K. Gibbs-McGlaston

I wrote my own reflection answers in the notebook, covering the three types of machines learning, my analysis of the Wine Classification results, a real-world application idea (phishing email detection in cybersecurity), and my key learnings. I also wrote a longer Module 3 reflection on the ML workflow, the model results, the challenges I faced, how this connects to my future work, and the questions I want to explore next.

Team Coordination

I communicated with my group by message about the assignment. I completed my own portion of the work individually and am only describing the work I personally did in this journal.

Marlon Roberts

For my contribution I ran through the analysis, after running the analysis I uploaded it on GitHub, from there I ran through the run test one more time to double check. After checking each cell to see if it was a complete test. Running the 25 code cells and troubleshooting any syntax or runtime errors. Making sure the machine learning pipeline runs smoothly from data collection through model evaluation without breaking. I created the file and repository, everyone contributed separately and had good outcomes. After running through the cells, I write my reflection and provide what I contributed.
